In today's CC, you need to create CSS classes for different styles of button which gives contextual meaning of what those buttons may do.

There are generally 6 types of buttons styles to convey meaning to the user:

1. Default Button (General purpose)
2. Primary Button (To convey a primary/main action)
3. Success Button (To convey a success action, like adding in the DB)
4. Info Button (To convey additional information action)
5. Warning Button (To convey warning level action action)
6. Danger Button (To convey danger level action, like delete actions)

You need to write CSS classes and show their usage by creating an HTML page and putting all those individual buttons as an example.

Note:

- Remember that you should define your CSS in an external file.
- It is not mandatory that your button should have the exact style like mentioned above. You can expand your creativity in that regard.

- However, it is mandatory to have relevant class name (like btndanger, btn-warning) in your CSS file.
